Note that the AX9170B device, although mentioned in this datasheet, has already been phased out and is presently no longer available.

Features

- Operating voltage: 2.5V~5.5V
- Minimal external components
- No external filter is required
- Low standby current (on power down mode)
- Excellent performance
- Tristate data output for MCU interface
- 3.58MHz crystal or ceramic resonator
- 1633Hz can be inhibited by the INH pin
- AX9170B: 18-pin DIP package
  AX9170D: 18-pin SOP package

General Description

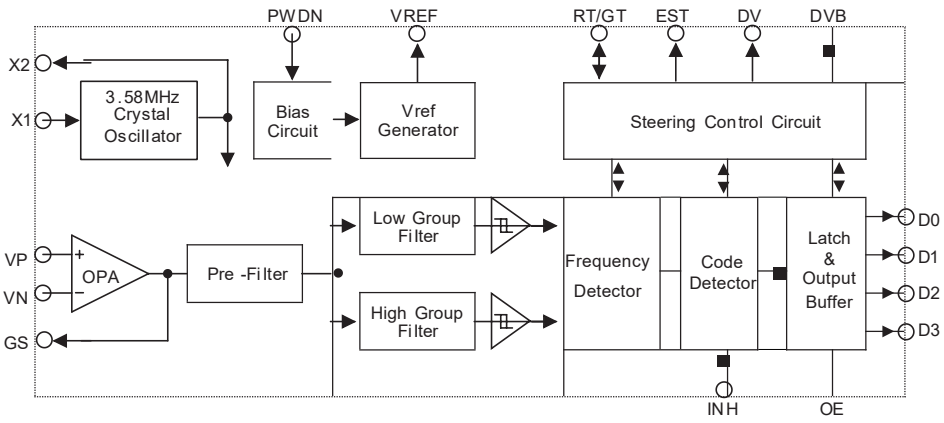
The AX9170B/Dare Dual Tone Multi Frequency (DTMF) receivers integrated with digital decoder and bandsplit filter functions as well as power-down mode and inhibit mode operations. Such devices use digital counting techniques to detect and decode all the 16 DTMF tone pairs into a 4-bit code output.

Highly accurate switched capacitor filters are implemented to divide tone signals into low and high group signals. A built-indialtone rejection circuit is provided to eliminate the need for pre-filtering.

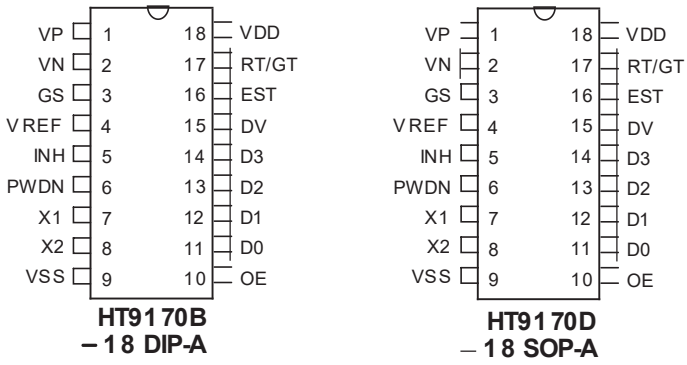
Selection Table

Function / Part No.	Operating Voltage	OSC Frequency	Tristate Data Output	Power Down	1633Hz Inhibit	DV	DVB	Package
AX9170B	2.5V~5.5V	3.58MHz	√	√	√	√	__	18 DIP
AX9170D	2.5V~5.5V	3.58MHz	√	√	√	√	__	18 SOP

Block Diagram



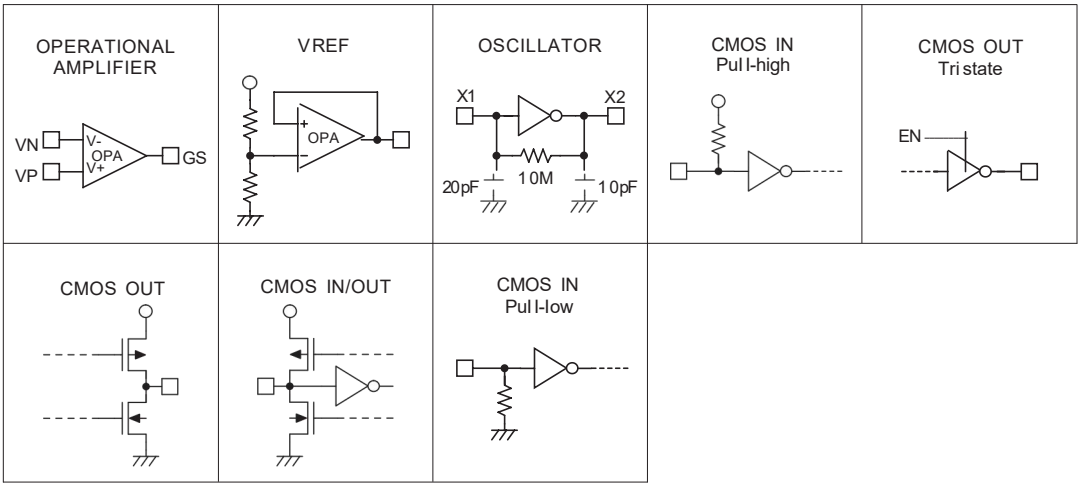
Pin Assignment



Pin Description

Pin Name	I/O	Internal Connection	Description
VP	I	Operational Amplifier	Operational amplifier non-inverting input
VN	I		Operational amplifier inverting input
GS	O		Operational amplifier output terminal
VREEF	O	VREF	Reference voltage output, normally $V_{DD}/2$
X1	I	oscillator	The system oscillator consists of an inverter,a bias resistor and the necessary load capacitor on chip. A standard 3.579545MHz crystal connected to X1 and X2 terminals implements the oscillator function.
X2	O		
PWDN	I	CMOS IN Pull-low	Active high. This enables the device to go into power down mode and inhibits the oscillator. This pin input is internally pulled down.
INH	I	CMOS IN Pull-low	Logic high. This inhibits the detection of tones representing characters A, B, C and D. This pin input is internally pulled down.
VSS	—	—	Negative power supply, ground
OE	I	CMOS IN Pull-high	D0~D3 output enable, high active
D0~D3	O	CMOS OUT Tristate	Receiving data output terminals OE=″ H″ : Output enable OE=″ L″ : High impedance
DV	O	CMOS OUT	Data valid output When the chip receives a valid tone (DTMF) signal, the DV goes high; otherwise it remains low.
EST	O	CMOS OUT	Early steering output (see Functional Description)
RT/GT	I/O	CMOS IN/OUT	Tone acquisition time and release time can be set through connection with external resistor and capacitor.
VDD	—	—	Positive power supply, 2.5V~5.5V for normal operation

Approximate internal connection circuits



Absolute Maximum Ratings

Supply Voltage ..... -0.3V to 6V

Input Voltage..... V_{SS}-0.3V to V_{DD}+0.3V

Storage Temperature .....-50oC to 125oC

Operating Temperature .....-20oC to 75oC

Note: These are stress ratings only. Stresses exceeding the range specified under "Absolute Maximum Ratings" may cause substantial damage to the device. Functional operation of this device at other conditions beyond those listed in the specification is not implied and prolonged exposure to extreme conditions may affect device reliability.

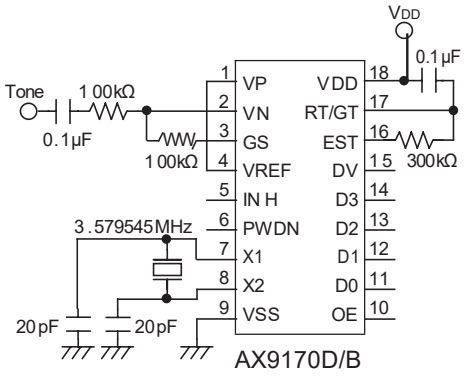

Figure 1. Test circuit

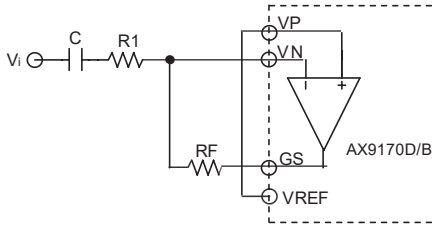
Functional Description

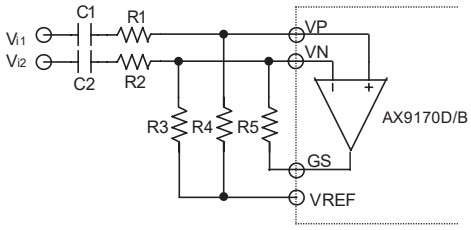
Overview

The AX9170B/D tone decoders consist of three band pass filters and two digital decode circuits to convert a tone (DTMF) signal into digital code output.

An operational amplifier is built-into adjust the input signal (refer to Figure 2).



(a) Standard input circuit



(b) Differential input circuit

Figure 2. Input operation for amplifier application circuits

The pre-filter is a band rejection filter which reduces the dialing tone from 350Hz to 400Hz.

The low group filter filters low group frequency signal output whereas the high group filter filters high group frequency signal output.

Each filter output is followed by a zero-crossing detector with hysteresis. When each signal amplitude at the output exceeds the specified level, it is transferred to full swing logic signal.

When input signals are recognized to be effective, DV becomes high, and the correct tone code (DTMF) digit is transferred.

Steering control circuit

The steering control circuit is used for measuring the effective signal duration and for protecting against drop out of valid signals. It employs the analog delay byexternal RC time-constant controlled by EST.

The timing is shown in Figure 3. The EST pin is normally low and draws the RT/GT pin to keep low through discharge of external RC. When a valid tone input is detected, EST goes high to charge RT/GT through RC.

When the voltage of RT/GT changes from 0 to V_{TRT} (2.35V for 5V supply), the input signal is effective, and the correct code will be created by the code detector. After D0~D3 are completely latched, DV output becomes high. When the voltage of RT/GT falls down from VDD to V_{TRT} (i.e.., when there is no input tone), DV output becomes low, and D0~D3 keeps data until a next valid tone input is produced.

By selecting adequate external RC value, the minimum acceptable input tone duration (t_{ACC}) and the minimum acceptable inter-tone rejection (t_{IR}) can be set. External components (R, C) are chosen by the formula (refer to Figure 5.):

$t_{ACC}=t_{DP}+t_{GTP}$;

$t_{IR}=t_{DA}+t_{GTA}$;

where t_{ACC}: Tone duration acceptable time
t_{DP}: EST output delay time (" L" → " H")
t_{GTP}: Tone present time
t_{IR}: Inter-digit pause rejection time

t_{DA}: EST output delay time (" H" → " L")
t_{GTA}: Tone absent time
